Warning

Ratio is not part of the Boost libraries.

Overview

How to Use This Documentation

This documentation makes use of the following naming and formatting conventions.

- Code is in `fixed width font` and is syntax-highlighted.
- Replaceable text that you will need to supply is in *italics*.
- Free functions are rendered in the code font followed by (), as in `free_function()`.

- If a name refers to a class template, it is specified like this: `class_template<>`; that is, it is in code font and its name is followed by `<>` to indicate that it is a class template.
- If a name refers to a function-like macro, it is specified like this: `MACRO()`; that is, it is uppercase in code font and its name is followed by `()` to indicate that it is a function-like macro. Object-like macros appear without the trailing `()`.
- Names that refer to *concepts* in the generic programming sense are specified in CamelCase.

Note

In addition, notes such as this one specify non-essential information that provides additional background or rationale.

Finally, you can mentally add the following to any code fragments in this document:

```
// Include all of Ratio files
#include <boost/ratio.hpp>
using namespace boost;
```

Motivation

Boost.Ratio aims to implement the compile time ratio facility in C++0x, as proposed in [N2661 - A Foundation to Sleep On](#). That document provides background and motivation for key design decisions and is the source of a good deal of information in this documentation.

Description

The **Boost.Ratio** library provides:

- A class template, `ratio`, for specifying compile time rational constants such as $1/3$ of a nanosecond or the number of inches per meter. `ratio` represents a compile time ratio of compile time constants with support for compile time arithmetic with overflow and division by zero protection
- It provides a textual representation of `boost::ratio<N, D>` in the form of a `std::basic_string`. Other types such as `boost::duration` can use these strings to aid in their I/O.

Users'Guide

Getting Started

Installing Ratio

Getting Boost.Ratio

You can get the last stable release of **Boost.Chrono** by downloading `chrono.zip` from the [Boost Vault](#). Directories `ratio`.

You can also access the latest (unstable?) state from the [Boost Sandbox](#). Just go to [here](#) and follow the instructions there for anonymous SVN access.

Where to install Boost.Ratio?

The simple way is to decompress (or checkout from SVN) the file in your `BOOST_ROOT` directory.

Othewise, if you decompress in a different directory, you will need to comment some lines, and uncomment and change others in the `build/Jamfile` and `test/Jamfile`. Sorry for this, but I have not reached yet to write a `Jamfile` that is able to work in both environements and use the `BOOST_ROOT` variable. Any help is welcome.

Building Boost.Ratio

Boost.Ratio is a header only library, so no need to compile anything.

Requirements

Boost.Ratio depends on some Boost libraries. For these specific parts you must use either Boost version 1.39.0 or the version in SVN trunk (even if older versions should work also).

In particular, **Boost.Ratio** depends on:

Boost.Config	for configuration purposes, ...
Boost.Integer	for cstdint conformance, and integer traits ...
Boost.MPL	for MPL Assert and bool, logical ...
Boost.StaticAssert	for STATIC_ASSERT, ...
Boost.TypeTraits	for is_base, is_convertible ...
Boost.Utility/EnableIf	for enable_if, ...

Building an executable that uses Boost.Ratio

No link is needed.

Exceptions safety

All functions in the library are exception-neutral and provide strong guarantee of exception safety as long as the underlying parameters provide it.

Thread safety

All functions in the library are thread-unsafe except when noted explicitly.

Tested compilers

The implementation will eventually work with most C++03 conforming compilers. Current version has been tested on:

Windows with

- MSVC 10.0
- MSVC 9.0 Express
- MSVC 8.0

Scientific Linux with

- GCC 4.1.2

Cygwin with

- GCC 3.4.4
- GCC 4.3.2

MinGW with

- GCC 4.4.0

- GCC 4.5.0

Initial version was tested on:

MacOS with GCC 4.2.4

Ubuntu Linux with GCC 4.2.4

Note

Please let us know how this works on other platforms/compilers.

Note

Please send any questions, comments and bug reports to [boost <at> lists <dot> boost <dot> org](mailto:boost@lists.boost.org).

Tutorial

`ratio` is a general purpose utility inspired by Walter Brown allowing one to easily and safely compute rational values at compile time. The `ratio` class catches all errors (such as divide by zero and overflow) at compile time. It is used in the `duration` and `time_point` classes to efficiently create units of time. It can also be used in other "quantity" libraries (both std-defined and user-defined), or anywhere there is a rational constant which is known at compile time. The use of this utility can greatly reduce the chances of run time overflow because the `ratio` (and any ratios resulting from `ratio` arithmetic) are always reduced to lowest terms.

`ratio` is a template taking two `intmax_ts`, with the second defaulted to 1. In addition to copy constructors and assignment, it only has two public members, both of which are static const `intmax_t`. One is the numerator of the `ratio` and the other is the denominator. The `ratio` is always normalized such that it is expressed in lowest terms, and the denominator is always positive. When the numerator is 0, the denominator is always 1.

Example:

```
typedef ratio<5, 3>    five_thirds;
// five_thirds::num == 5, five_thirds::den == 3

typedef ratio<25, 15> also_five_thirds;
// also_five_thirds::num == 5, also_five_thirds::den == 3

typedef ratio_divide<five_thirds, also_five_thirds>::type one;
// one::num == 1, one::den == 1
```

This facility also includes convenience typedefs for the SI prefixes `atto` through `exa` corresponding to their internationally recognized definitions (in terms of `ratio`). This is a tremendous syntactic convenience. It will prevent errors in specifying constants as one no longer has to double count the number of zeros when trying to write million or billion.

Example:

```
typedef ratio_multiply<ratio<5>, giga>::type _5giga;
// _5giga::num == 5000000000, _5giga::den == 1

typedef ratio_multiply<ratio<5>, nano>::type _5nano;
// _5nano::num == 1, _5nano::den == 200000000
```

Examples

SI-units

Type-safe "physics" code interoperating with boost::chrono:: duration types and taking advantage of the boost::ratio infrastructure and design philosophy.

length - mimics boost::chrono:: duration except restricts representation to double. Uses boost::ratio facilities for length units conversions.

```
template <class Ratio>
class length {
private:
    double len_;
public:
    typedef Ratio ratio;
    length() : len_(1) {}
    length(const double& len) : len_(len) {}

    template <class R>
    length(const length<R>& d)
        : len_(d.count() * boost::ratio_divide<Ratio, R>::type::den /
                boost::ratio_divide<Ratio, R>::type::num) {}

    double count() const {return len_;}

    length& operator+=(const length& d) {len_ += d.count(); return *this;}
    length& operator-=(const length& d) {len_ -= d.count(); return *this;}

    length operator+() const {return *this;}
    length operator-() const {return length(-len_);}

    length& operator*=(double rhs) {len_ *= rhs; return *this;}
    length& operator/=(double rhs) {len_ /= rhs; return *this;}
};
```

Sparse sampling of length units

```
typedef length<boost::ratio<1> > meter; // set meter as "unity"
typedef length<boost::centi> centimeter; // 1/100 meter
typedef length<boost::kilo> kilometer; // 1000 meters
typedef length<boost::ratio<254, 10000> > inch; // 254/10000 meters
```

length takes ratio instead of two integral types so that definitions can be made like so:

```
typedef length<boost::ratio_multiply<boost::ratio<12>, inch::ratio>::type> foot; // 12 inchs
typedef length<boost::ratio_multiply<boost::ratio<5280>, foot::ratio>::type> mile; // 5280 feet
```

Need a floating point definition of seconds

```
typedef boost::chrono:: duration<double> seconds; // unity
```

Demo of (scientific) support for sub-nanosecond resolutions

```
typedef boost::chrono:: duration<double, boost::pico> picosecond; // 10^-12 seconds
typedef boost::chrono:: duration<double, boost::femto> femtosecond; // 10^-15 seconds
typedef boost::chrono:: duration<double, boost::atto> attosecond; // 10^-18 seconds
```

A very brief proof-of-concept for SIUnits-like library. Hard-wired to floating point seconds and meters, but accepts other units.

```
template <class R1, class R2>
class quantity
{
    double q_;
public:
    typedef R1 time_dim;
    typedef R2 distance_dim;
    quantity() : q_(1) {}

    double get() const {return q_;}
    void set(double q) {q_ = q;}
};

template <>
class quantity<boost::ratio<1>, boost::ratio<0> >
{
    double q_;
public:
    quantity() : q_(1) {}
    quantity(seconds d) : q_(d.count()) {} // note: only User1::seconds needed here

    double get() const {return q_;}
    void set(double q) {q_ = q;}
};

template <>
class quantity<boost::ratio<0>, boost::ratio<1> >
{
    double q_;
public:
    quantity() : q_(1) {}
    quantity(meter d) : q_(d.count()) {} // note: only User1::meter needed here

    double get() const {return q_;}
    void set(double q) {q_ = q;}
};

template <>
class quantity<boost::ratio<0>, boost::ratio<0> >
{
    double q_;
public:
    quantity() : q_(1) {}
    quantity(double d) : q_(d) {}

    double get() const {return q_;}
    void set(double q) {q_ = q;}
};
```

Example of SI-Units

```

typedef quantity<boost::ratio<0>, boost::ratio<0> > Scalar;
typedef quantity<boost::ratio<1>, boost::ratio<0> > Time;           // second
typedef quantity<boost::ratio<0>, boost::ratio<1> > Distance;       // meter
typedef quantity<boost::ratio<-1>, boost::ratio<1> > Speed;         // meter/second
typedef quantity<boost::ratio<-2>, boost::ratio<1> > Acceleration;  // meter/second^2

```

Quantity arithmetics

```

template <class R1, class R2, class R3, class R4>
quantity<typename boost::ratio_subtract<R1, R3>::type,
        typename boost::ratio_subtract<R2, R4>::type>
operator/(const quantity<R1, R2>& x, const quantity<R3, R4>& y)
{
    typedef quantity<typename boost::ratio_subtract<R1, R3>::type,
                    typename boost::ratio_subtract<R2, R4>::type> R;
    R r;
    r.set(x.get() / y.get());
    return r;
}

template <class R1, class R2, class R3, class R4>
quantity<typename boost::ratio_add<R1, R3>::type,
        typename boost::ratio_add<R2, R4>::type>
operator*(const quantity<R1, R2>& x, const quantity<R3, R4>& y)
{
    typedef quantity<typename boost::ratio_add<R1, R3>::type,
                    typename boost::ratio_add<R2, R4>::type> R;
    R r;
    r.set(x.get() * y.get());
    return r;
}

template <class R1, class R2>
quantity<R1, R2>
operator+(const quantity<R1, R2>& x, const quantity<R1, R2>& y)
{
    typedef quantity<R1, R2> R;
    R r;
    r.set(x.get() + y.get());
    return r;
}

template <class R1, class R2>
quantity<R1, R2>
operator-(const quantity<R1, R2>& x, const quantity<R1, R2>& y)
{
    typedef quantity<R1, R2> R;
    R r;
    r.set(x.get() - y.get());
    return r;
}

```

Example type-safe physics function

```
Distance
compute_distance(Speed v0, Time t, Acceleration a)
{
    return v0 * t + Scalar(.5) * a * t * t; // if a units mistake is made here it won't compile
}
```

Exercise example type-safe physics function and show interoperation of custom time durations (User1::seconds) and standard time durations (boost::hours). Though input can be arbitrary (but type-safe) units, output is always in SI-units (a limitation of the simplified Units lib demoed here).

```
int main()
{
    typedef boost::ratio<8, BOOST_INTMAX_C(0x7FFFFFFFD)> R1;
    typedef boost::ratio<3, BOOST_INTMAX_C(0x7FFFFFFFD)> R2;
    typedef User1::quantity<boost::ratio_subtract<boost::ratio<0>, boost::ratio<1>>::type,
        boost::ratio_subtract<boost::ratio<1>, boost::ratio<0>>::type> RR;
    typedef boost::ratio_subtract<R1, R2>::type RS;
    std::cout << RS::num << '/' << RS::den << '\n';

    std::cout << "*****\n";
    std::cout << "* testUser1 *\n";
    std::cout << "*****\n";
    User1::Distance d( User1::mile(110) );
    User1::Time t( boost::chrono:: hours(2) );

    RR r=d / t;
    //r.set(d.get() / t.get());

    User1::Speed rc= r;

    User1::Speed s = d / t;
    std::cout << "Speed = " << s.get() << " meters/sec\n";
    User1::Acceleration a = User1::Distance( User1::foot(32.2) ) / User1::Time() / User1::Time();
    std::cout << "Acceleration = " << a.get() << " meters/sec^2\n";
    User1::Distance df = compute_distance(s, User1::Time( User1::seconds(0.5) ), a);
    std::cout << "Distance = " << df.get() << " meters\n";
    std::cout << "There are "
        << User1::mile::ratio::den << '/' << User1::mile::ratio::num << " miles/meter";
    User1::meter mt = 1;
    User1::mile mi = mt;
    std::cout << " which is approximately " << mi.count() << '\n';
    std::cout << "There are "
        << User1::mile::ratio::num << '/' << User1::mile::ratio::den << " meters/mile";
    mi = 1;
    mt = mi;
    std::cout << " which is approximately " << mt.count() << '\n';
    User1::attosecond as(1);
    User1::seconds sec = as;
    std::cout << "1 attosecond is " << sec.count() << " seconds\n";
    std::cout << "sec = as; // compiles\n";
    sec = User1::seconds(1);
    as = sec;
    std::cout << "1 second is " << as.count() << " attoseconds\n";
    std::cout << "as = sec; // compiles\n";
    std::cout << "\n";
    return 0;
}
```

See the source file test/ratio_test.cpp

Reference

Header `<boost/ratio.hpp>`

`ratio` is a facility which is useful in specifying compile time rational constants. Compile time rational arithmetic is supported with protection against overflow and divide by zero. Such a facility is very handy when needing to efficiently represent 1/3 of a nanosecond, or specifying an inch in terms of meters (for example 254/10000 meters - which `ratio` will reduce to 127/5000 meters).

```

// configuration macros
#define BOOST_RATIO_USES_STATIC_ASSERT
#define BOOST_RATIO_USES_MPL_ASSERT
#define BOOST_RATIO_USES_ARRAY_ASSERT

namespace boost {

    template <boost::intmax_t N, boost::intmax_t D = 1> class ratio;

    // ratio arithmetic
    template <class R1, class R2> struct ratio_add;
    template <class R1, class R2> struct ratio_subtract;
    template <class R1, class R2> struct ratio_multiply;

    typedef ratio<1000000000LL, 1LL> giga;
    typedef ratio<1000000000000LL, 1LL> tera;
    typedef ratio<1000000000000000LL, 1LL> peta;
    typedef ratio<1000000000000000000LL, 1LL> exa;
}

```

Configuration macros

When `BOOST_NO_STATIC_ASSERT` is defined, the user can select the way static assertions are reported. Define

- `BOOST_RATIO_USES_STATIC_ASSERT`: define it if you want to use `Boost.StaticAssert`
- `BOOST_RATIO_USES_MPL_ASSERT`: define it if you want to use `Boost.MPL` static assertions
- `BOOST_RATIO_USES_ARRAY_ASSERT`: define it if you want to use internal static assertions

The default behavior is as `BOOST_RATIO_USES_ARRAY_ASSERT` was defined.

When `BOOST_RATIO_USES_MPL_ASSERT` is not defined the following symbols are defined as

```
#define BOOST_RATIO_OVERFLOW_IN_ADD "overflow in ratio add"
#define BOOST_RATIO_OVERFLOW_IN_SUB "overflow in ratio sub"
#define BOOST_RATIO_OVERFLOW_IN_MUL "overflow in ratio mul"
#define BOOST_RATIO_OVERFLOW_IN_DIV "overflow in ratio div"
#define BOOST_RATIO_RATIO_NUMERATOR_IS_OUT_OF_RANGE "ratio numerator is out of range"
#define BOOST_RATIO_RATIO_DIVIDE_BY_0 "ratio divide by 0"
#define BOOST_RATIO_RATIO_DENOMINATOR_IS_OUT_OF_RANGE "ratio denominator is out of range"
```

Depending on the static assertion used system you will have an hint of the failing assertion either through the symbol or through the texte.

Class Template `ratio<>`

```
template <boost::intmax_t N, boost::intmax_t D>
class ratio {
public:
    static const boost::intmax_t num;
    static const boost::intmax_t den;
    typedef ratio<num, den> type;

    ratio() = default;

    template <intmax_t _N2, intmax_t _D2>
    ratio(const ratio<_N2, _D2>&);

    template <intmax_t _N2, intmax_t _D2>
    ratio& operator=(const ratio<_N2, _D2>&) {return *this;}
};
```

A diagnostic will be emitted if `ratio` is instantiated with `D == 0`, or if the absolute value of `N` or `D` can not be represented. **Note:** These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. In a two's complement representation, this excludes the most negative value.

Let `gcd` denote the greatest common divisor of `N`'s absolute value and of `D`'s absolute value.

- `num` has the value `sign(N)*sign(D)*abs(N)/gcd`.
- `den` has the value `abs(D)/gcd`.

The nested typedef `type` denotes the normalized form of this `ratio` type. It should be used when the template parameters doesn't give a normalized form.

Two `ratio` classes `ratio<N1,D1>` and `ratio<N2,D2>` have the same normalized form if `ratio<N1,D1>::type` is the same type as `ratio<N2,D2>::type`

Construction and assignment

```
template <intmax_t N2, intmax_t D2>
ratio(const ratio<N2, D2>& r);
```

Effects: Constructs a `ratio` object.

Remarks: This constructor will not participate in overload resolution unless `r` has the same normalized form as `*this`.

```
template <intmax_t N2, intmax_t D2>
ratio& operator=(const ratio<N2, D2>& r);
```

Effects: Assigns a `ratio` object.

Returns: *this.

Remarks: This operator will not participate in overload resolution unless `r` has the same normalized form as `*this`.

ratio arithmetic

For each of the class templates in this clause, each template parameter refers to a `ratio`. If the implementation is unable to form the indicated `ratio` due to overflow, a diagnostic will be issued.

```
template <class R1, class R2> struct ratio_add {  
    typedef [ /see below ] type;  
};
```

The nested typedef `type` is a synonym for `ratio<R1::num * R2::den + R2::num * R1::den, R1::den * R2::den>::type`.

```
template <class R1, class R2> struct ratio_subtract {  
    typedef [ /see below ] type;  
};
```

The nested typedef `type` is a synonym for `ratio<R1::num * R2::den - R2::num * R1::den, R1::den * R2::den>::type`.

```
template <class R1, class R2> struct ratio_multiply {  
    typedef [ /see below ] type;  
};
```

The nested typedef `type` is a synonym for `ratio<R1::num * R2::num, R1::den * R2::den>::type`.

```
template <class R1, class R2> struct ratio_divide {  
    typedef [ /see below ] type;  
};
```

The nested typedef `type` is a synonym for `ratio<R1::num * R2::den, R2::num * R1::den>::type`.

ratio comparison

```
template <class R1, class R2> struct ratio_equal  
    : public boost::integral_constant<bool, [ /see below ] > {};
```

If `R1::num = R2::num && R1::den = R2::den`, `ratio_equal` derives from `true_type`, else derives from `false_type`.

```
template <class R1, class R2>  
struct ratio_less  
    : public boost::integral_constant<bool, [ /see below ] > {};
```

If `R1::num * R2::den < R2::num * R1::den`, `ratio_less` derives from `true_type`, else derives from `false_type`.

```

template <class R1, class R2> struct ratio_not_equal
    : public boost::integral_constant<bool, !ratio_equal<R1, R2>::value> {};

template <class R1, class R2> struct ratio_less_equal
    : public boost::integral_constant<bool, !ratio_less<R2, R1>::value> {};

template <class R1, class R2> struct ratio_greater
    : public boost::integral_constant<bool, ratio_less<R2, R1>::value> {};

template <class R1, class R2> struct ratio_greater_equal
    : public boost::integral_constant<bool, !ratio_less<R1, R2>::value> {};

```

SI typedefs

```

// convenience SI typedefs
typedef ratio<1LL, 1000000000000000000LL> atto;
typedef ratio<1LL, 1000000000000000LL> femto;
typedef ratio<1LL, 1000000000000LL> pico;
typedef ratio<1LL, 1000000000LL> nano;
typedef ratio<1LL, 1000000LL> micro;
typedef ratio<1LL, 1000LL> milli;
typedef ratio<1LL, 100LL> centi;
typedef ratio<1LL, 10LL> deci;
typedef ratio<10LL, 1LL> deca;
typedef ratio<100LL, 1LL> hecto;
typedef ratio<1000LL, 1LL> kilo;
typedef ratio<1000000LL, 1LL> mega;
typedef ratio<1000000000LL, 1LL> giga;
typedef ratio<1000000000000LL, 1LL> tera;
typedef ratio<1000000000000000LL, 1LL> peta;
typedef ratio<1000000000000000000LL, 1LL> exa;

```

Limitations and Extensions

Next follows limitation respect to the C++0x recommendations:

- Four of the typedefs in the recommendation which can be conditionally supported are not supported: yocto, zepto, zetta and yotta.

```

typedef ratio<1, 1000000000000000000000> yocto; // conditionally supported
typedef ratio<1, 100000000000000000000> zepto; // conditionally supported
typedef ratio<1000000000000000000000, 1> zetta; // conditionally supported
typedef ratio<1000000000000000000000000, 1> yotta; // conditionally supported

```

- Ratio values should be constexpr:** constexpr don't used as no compiler supports it today. const is used instead when appropriated.
- Rational Arithmetic should use template aliases:** In the absence of compiler support of template aliases the C++03 emulation define a nested typedef type.

The current implementation provides in addition:

- the **copy constructor and assignement between ratios having the same normalized form.**

Header `<boost/ratio_io.hpp>`

It provides a textual representation of `boost::ratio<N, D>` in the form of a `std::basic_string`. Other types such as `boost::duration` can use these strings to aid in their I/O.

This source has been adapted from the experimental header `<ratio_io>` from Howard Hinnant. Porting to Boost has been trivial.

```
namespace boost {  
  
    template <class Ratio, class CharT>  
    struct ratio_string  
    {  
        static std::basic_string<CharT> short_name() {return long_name();}  
        static std::basic_string<CharT> long_name();  
    };  
  
}
```

For each `ratio<N, D>` there exists a `ratio_string<ratio<N, D>, CharT>` for which you can query two strings: `short_name` and `long_name`. For those ratio's that correspond to an [SI prefix](#) `long_name` corresponds to the internationally recognized prefix, stored as a `basic_string<CharT>`. For example `ratio_string<mega, char>::long_name()` returns `string("mega")`. For those ratio's that correspond to an [SI prefix](#) `short_name` corresponds to the internationally recognized symbol, stored as a `basic_string<CharT>`. For example `ratio_string<mega, char>::short_name()` returns `string("M")`. For all other ratio's, both `long_name()` and `short_name()` return a `basic_string` containing `"[ratio::num/ratio::den]"`.

`ratio_string<ratio<N, D>, CharT>` is only defined for four character types:

- `char`
- `char16_t`
- `char32_t`
- `wchar_t`

When the character is `char`, UTF-8 will be used to encode the names. When the character is `char16_t`, UTF-16 will be used to encode the names. When the character is `char32_t`, UTF-32 will be used to encode the names. When the character is `wchar_t`, the encoding will be UTF-16 if `wchar_t` is 16 bits, and otherwise UTF-32.

The `short_name` for micro is defined by [Unicode](#) to be U+00B5.

Examples:

```
#include <boost/ratio/ratio_io.hpp>
#include <iostream>

int main()
{
    using namespace std;
    using namespace boost;

    cout << "ratio_string<deca, char>::long_name() = "
         << ratio_string<deca, char>::long_name() << '\n';
    cout << "ratio_string<deca, char>::short_name() = "
         << ratio_string<deca, char>::short_name() << '\n';

    cout << "ratio_string<giga, char>::long_name() = "
         << ratio_string<giga, char>::long_name() << '\n';
    cout << "ratio_string<giga, char>::short_name() = "
         << ratio_string<giga, char>::short_name() << '\n';

    cout << "ratio_string<ratio<4, 6>, char>::long_name() = "
         << ratio_string<ratio<4, 6>, char>::long_name() << '\n';
    cout << "ratio_string<ratio<4, 6>, char>::short_name() = "
         << ratio_string<ratio<4, 6>, char>::short_name() << '\n';
}
```

The output will be

```
ratio_string<deca, char>::long_name() = deca
ratio_string<deca, char>::short_name() = da
ratio_string<giga, char>::long_name() = giga
ratio_string<giga, char>::short_name() = G
ratio_string<ratio<4, 6>, char>::long_name() = [2/3]
ratio_string<ratio<4, 6>, char>::short_name() = [2/3]
```

Appendices

Appendix A: History

Version 0.2.0, September 22, 2010

Features:

- Added ratio_string traits.

Fixes:

- ratio_less overflow avoided following the algorithm from libc++.

Test:

- A more complete test has been included adapted from the test of from libc++/ratio.

Version 0.1.0, September 10, 2010

Features:

- Ratio has been extracted from Boost.Chrono.

Appendix B: Rationale

Why ratio needs CopyConstruction and Assignment from ratios having the same normalized form

Current **N3000** doesn't allow to copy-construct or assign ratio instances of ratio classes having the same normalized form.

This simple example

```
ratio<1,3> r1;
ratio<3,9> r2;
r1 = r2; // (1)
```

fails to compile in (1). Other example

```
ratio<1,3> r1;
ratio_subtract<ratio<2,3>,ratio<1,3>> r2=r1; // (2)
```

The type of `ratio_subtract<ratio<2,3>,ratio<1,3>>` could be `ratio<3,9>` so the compilation could fail in (2). It could also be `ratio<1,3>` and the compilation succeeds.

Why ratio needs the nested normalizer typedef type

In **N3000** 20.4.2 and similar clauses

*3 The nested typedef type shall be a synonym for `ratio<T1, T2>` where $T1$ has the value $R1::num * R2::den - R2::num * R1::den$ and $T2$ has the value $R1::den * R2::den$.*

The meaning of synonym let think that the result should be a normalized ratio equivalent to `ratio<T1, T2>`, but there is not an explicit definition of what synonym means in this context.

If the CopyConstruction and Assignment ([**LWG 1281**]) is not added we need a typedef for accessing the normalized ratio, and change 20.4.2 to return only this normalized result. In this case the user will need to

```
ratio<1,3>::type r1;
ratio<3,9>::type r2;
r1 = r2; // compiles as both types are the same.
```

Appendix C: Implementation Notes

How Boost.Ratio manage with compile-time rational arithmetic overflow?

When the result is representable, but a simple application of arithmetic rules would result in overflow, e.g. `ratio_multiply<ratio<INTMAX_MAX, 2>, ratio<2, INTMAX_MAX>>` can be reduced to `ratio<1, 1>`, but the direct result of `ratio<INTMAX_MAX*2, INTMAX_MAX*2>` would result in overflow.

Boost.Ratio has implemented some simplifications in order to reduce the possibility of overflow, but these don't take care of all possible cases. For example the preceding example doesn't work now.

In order to take care of this case we could apply this kind of simplification:

```
simplify< fraction<times<A,B>, times<C,D> > > > ::=
  case gcd(A,C) > 1 simplify< fraction<times<A/gcd(A,C),B>, times<C/gcd(A,C),D>>>
  case gcd(A,D) > 1 simplify< fraction<times<A/gcd(A,D),B>, times<C,D/gcd(A,D)>>>
  case gcd(B,C) > 1 simplify< fraction<times<A,B/gcd(B,C)>, times<C/gcd(B,C),D>>>
  case gcd(B,D) > 1 simplify< fraction<times<A,B/gcd(B,D)>, times<C,D/gcd(B,D)>>>
  otherwise ratio<A*B, C*D>
```

While this works in some cases, a more general factorization algorithm will be needed to manage with all the cases. Whether we should manage with them is an open question, as the compile times will be increased strongly to cover some causal cases.

Appendix D: FAQ

Appendix E: Acknowledgements

The library's code was derived from Howard Hinnant's `time2_demo` prototype. Many thanks to Howard for making his code available under the Boost license. The original code was modified by Beman Dawes to conform to Boost conventions.

`time2_demo` contained this comment:

Much thanks to Andrei Alexandrescu, Walter Brown, Peter Dimov, Jeff Garland, Terry Golubiewski, Daniel Krugler, Anthony Williams.

Thanks to Adrew Chinoff for his help polishing the documentation.

Appendix F: Tests

In order to test you need to do.

```
bjam libs/ratio/test
```

You can also run a specific suite of test by doing

```
cd libs/chrono/test
bjam ratio
```

ratio

Name	kind	Description	Result	Ticket
typedefs.pass	run	check the num/den are correct for the predefined typedefs	Pass	#
ratio.pass	run	check the num/den are correctly simplified	Pass	#
ratio1.fail	compile-fails	The template argument D shall not be zero	Pass	#
ratio2.fail	compile-fails	the absolute values of the template arguments N and D shall be representable by type <code>intmax_t</code>	Pass	#
ratio3.fail	compile-fails	the absolute values of the template arguments N and D shall be representable by type <code>intmax_t</code>	Pass	#

comparison

Name	kind	Description	Result	Ticket
ratio_equal.pass	run	check ratio_equal metafunction class	Pass	#
ratio_not_equal.pass	run	check ratio_not_equal metafunction class	Pass	#
ratio_less.pass	run	check ratio_less metafunction class	Pass	#
ratio_less_equal.pass	run	check ratio_less_equal metafunction class	Pass	#
ratio_greater.pass	run	check ratio_greater metafunction class	Pass	#
ratio_greater_equal.pass	run	check ratio_greater_equal metafunction class	Pass	#

arithmetic

Name	kind	Description	Result	Ticket
